

# Turbulence Impact Mitigation Workshop 3

## Next Generation World Area Forecast System Turbulence Forecasts

*Presented by Claire Bartholomew, WAFC London and  
Matt Strahan, WAFC Washington*

# Current WAFS Turbulence Product

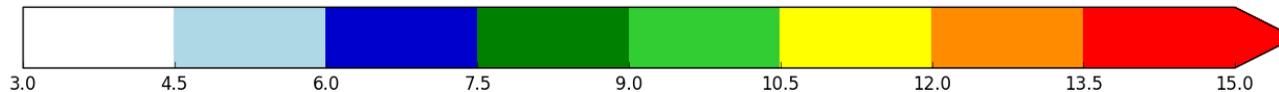

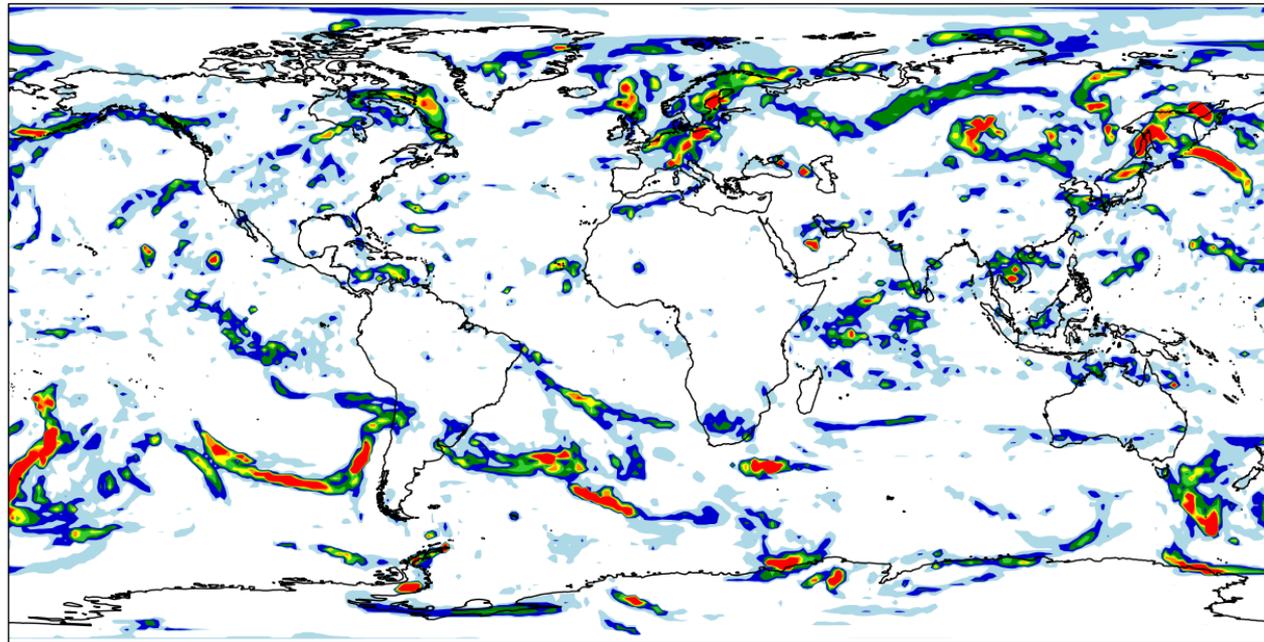

Maximum Blended CAT

Two provider states,  
WAFC London and  
WAFC Washington

Max and a mean  
turbulence “potential”

1.25 degree horizontal  
resolution grid. T+6 to  
T+36 3 hour time steps

# WAFS Improvement Schedule

## 2020

- Turbulence Severity (EDR)
- Horizontal resolution increased to 0.25 degrees

## 2022

- Temporal resolution T+6 to T+24 in 1 hour increments
- Temporal resolution T+27 to T+48 in 3 hour increments

## 2024

- Probabilistic Severity (EDR)

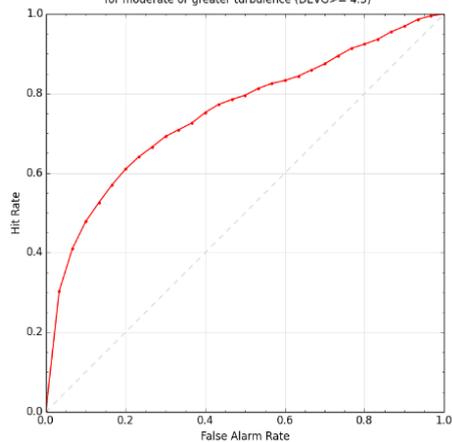

# ROC Plots of GTG vs current WAFS

## WAFS

ROC for global WAFS CAT forecasts against aircraft data,  
Jul 2016 - Jun 2017 Area World : WMO CBS World area 90N-90S 180W-180E T+24,  
for moderate or greater turbulence (DEVG >= 4.5)

## GTG

ROC for global WAFS CAT forecasts against aircraft data,  
Jul 2016 - Jun 2017 Area World : WMO CBS World area 90N-90S 180W-180E T+24,  
for moderate or greater turbulence (DEVG >= 4.5)

© Crown Copyright 2017. Source: Met Office

- GTG fractionally higher but this is lower resolution ensemble data (control).
- Next trial (underway) uses (~10km) global deterministic data

# Turbulence Climatology: AIM

- To generate MOG turbulence climatology using database of automated aircraft observations
- To attempt identification of turbulence events generated by convection and mountain waves, and start to build a climatology of these

Study will ultimately aim:

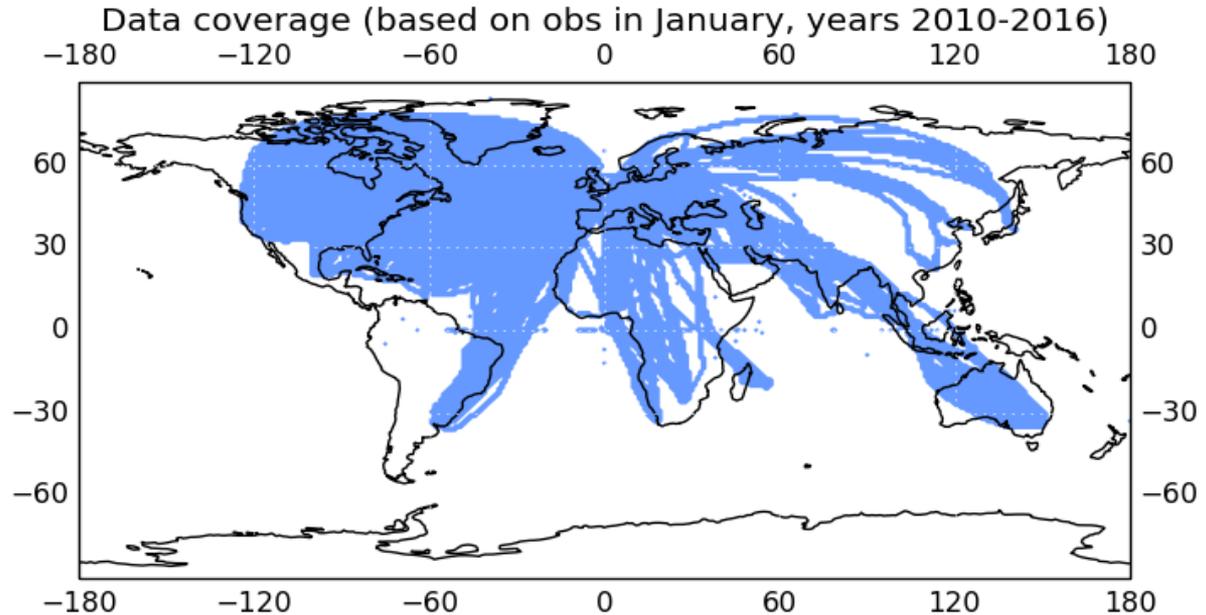

- To identify areas where MOG turbulence is more likely, for use in the aviation community
- To provide a basis for future studies of turbulence
- To aid future development of turbulence indicators

# Aircraft observational data used

- Archive of automated aircraft measurements

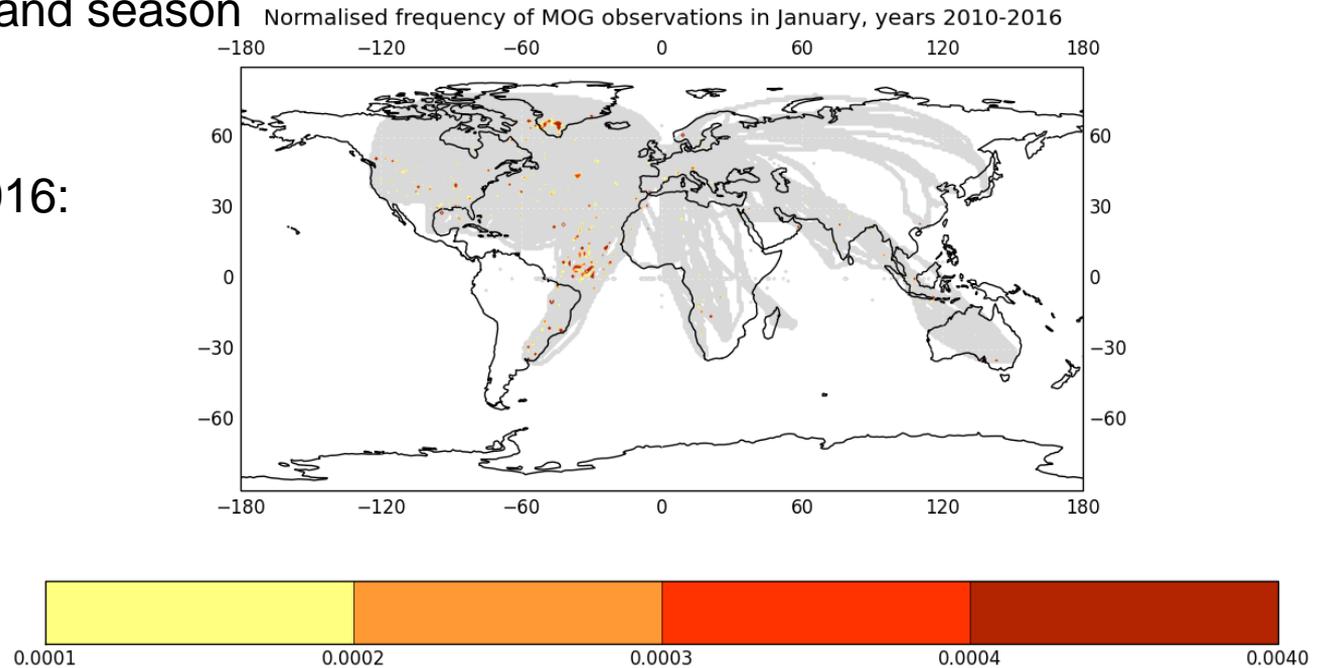

- Global Aircraft Data Set (GADS) – aircraft observations
- ~13 years worth of data available, but need to re-quality control the data for use. Currently 7 years of data has been re-qc'ed
- Data includes vertical acceleration, from which DEVG is calculated
- Main area of coverage indicated below:

# Percentage of Turbulence Obs that are Moderate or Greater (MOG)

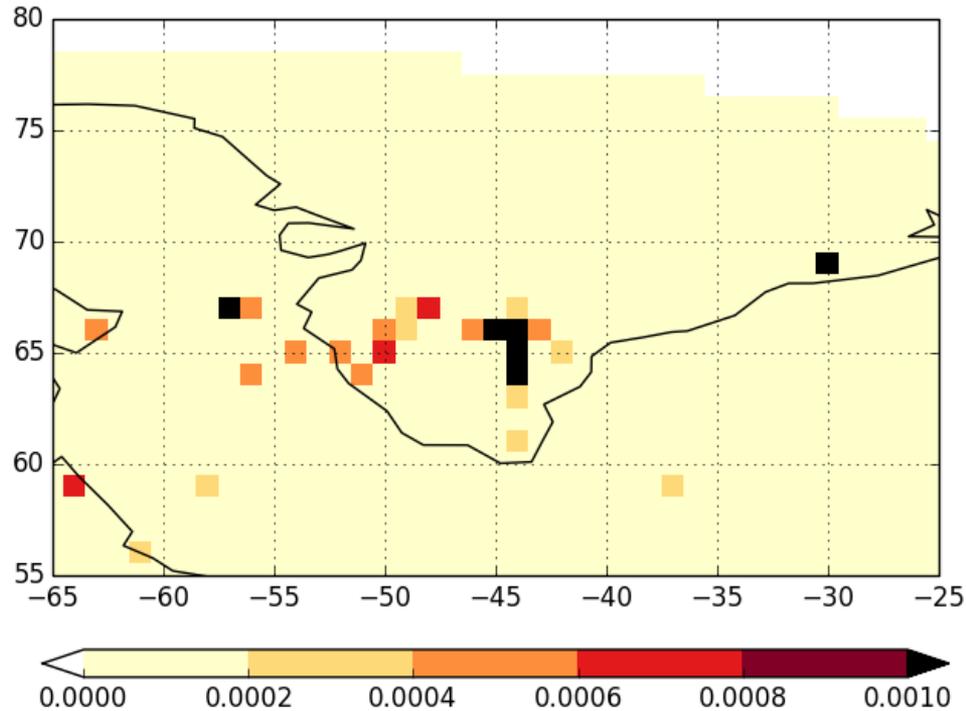

- Calculation of (total number of MOG obs)/(total number of obs) in a  $1^\circ \times 1^\circ$  grid square
- For each month and season for 7 years
- Initial results for January 2010-2016:

# Turbulence Hotspots - Greenland

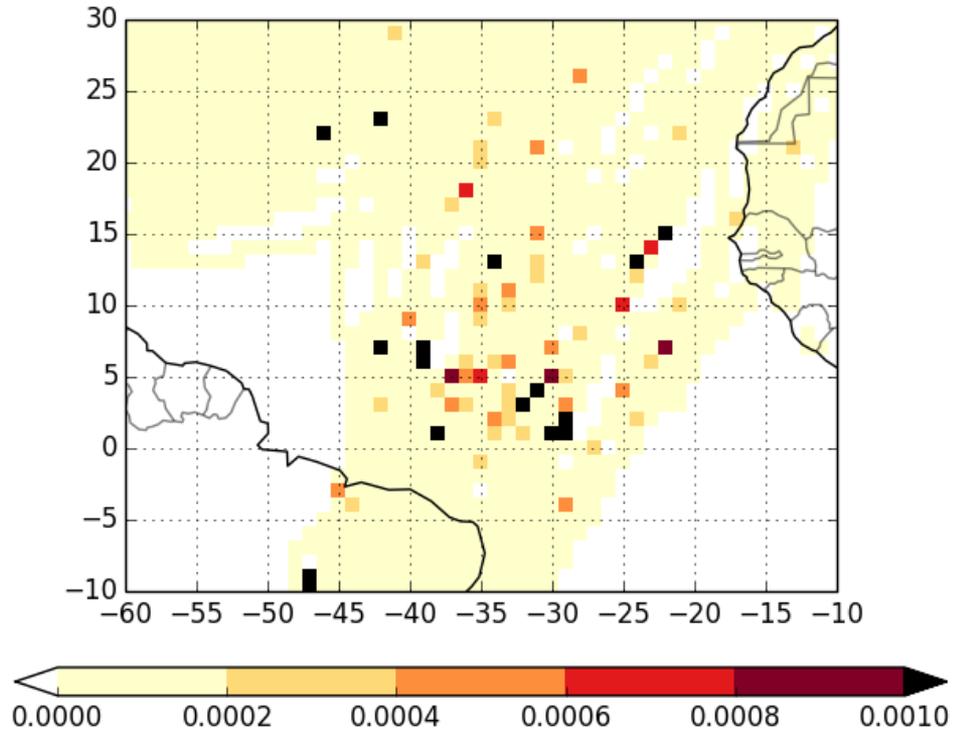

Greenland: January 2010-2016

# Turbulence Hotspots -Tropical Atlantic

Tropical Atlantic: January 2010-2016

# Next Steps

Combining with other airlines data

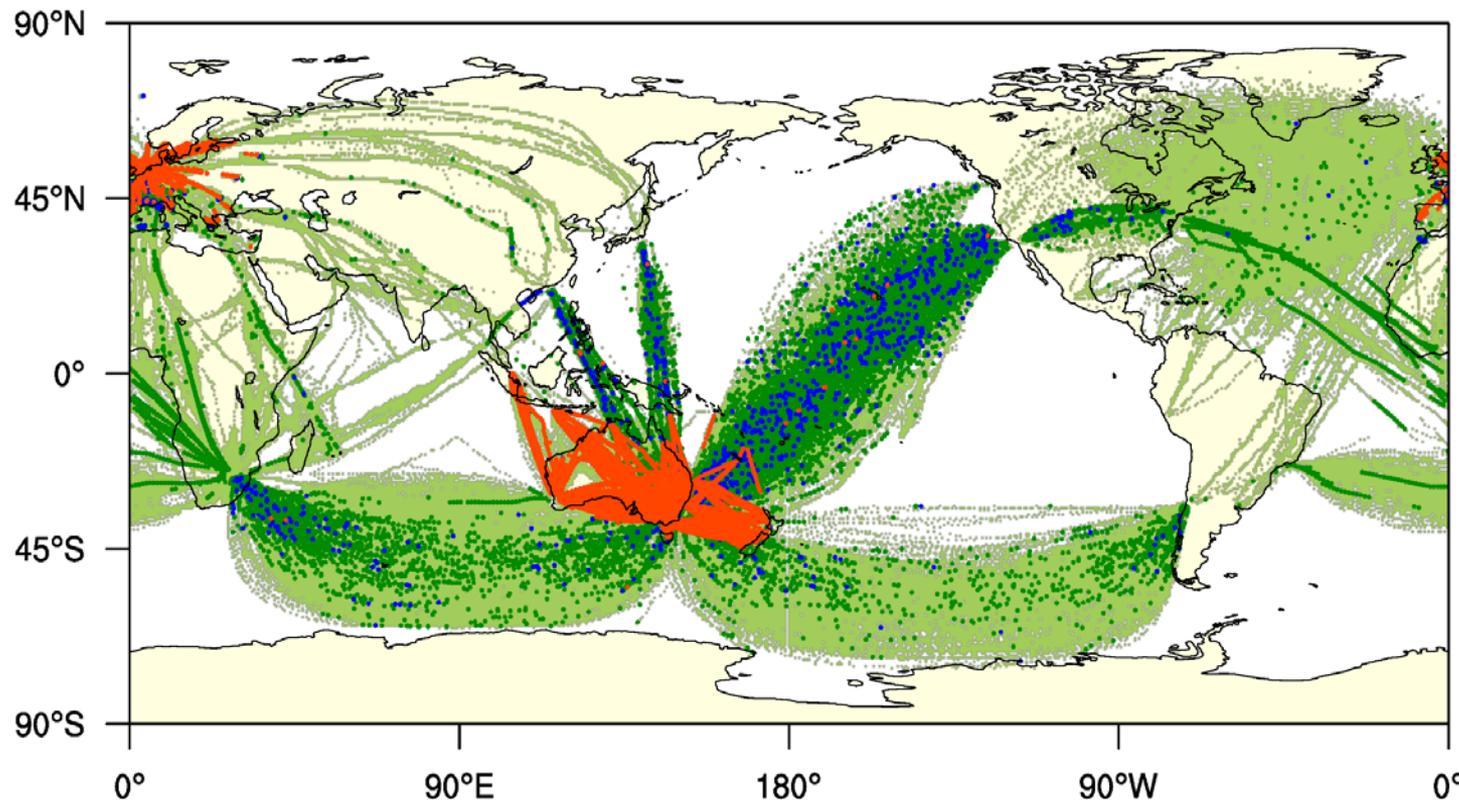

Using to verify WAFS turbulence diagnostic

Further QC of more recent aircraft observations

# Issues on quality of AMDAR data

● NIL ● LGT ● MOD ● SEV

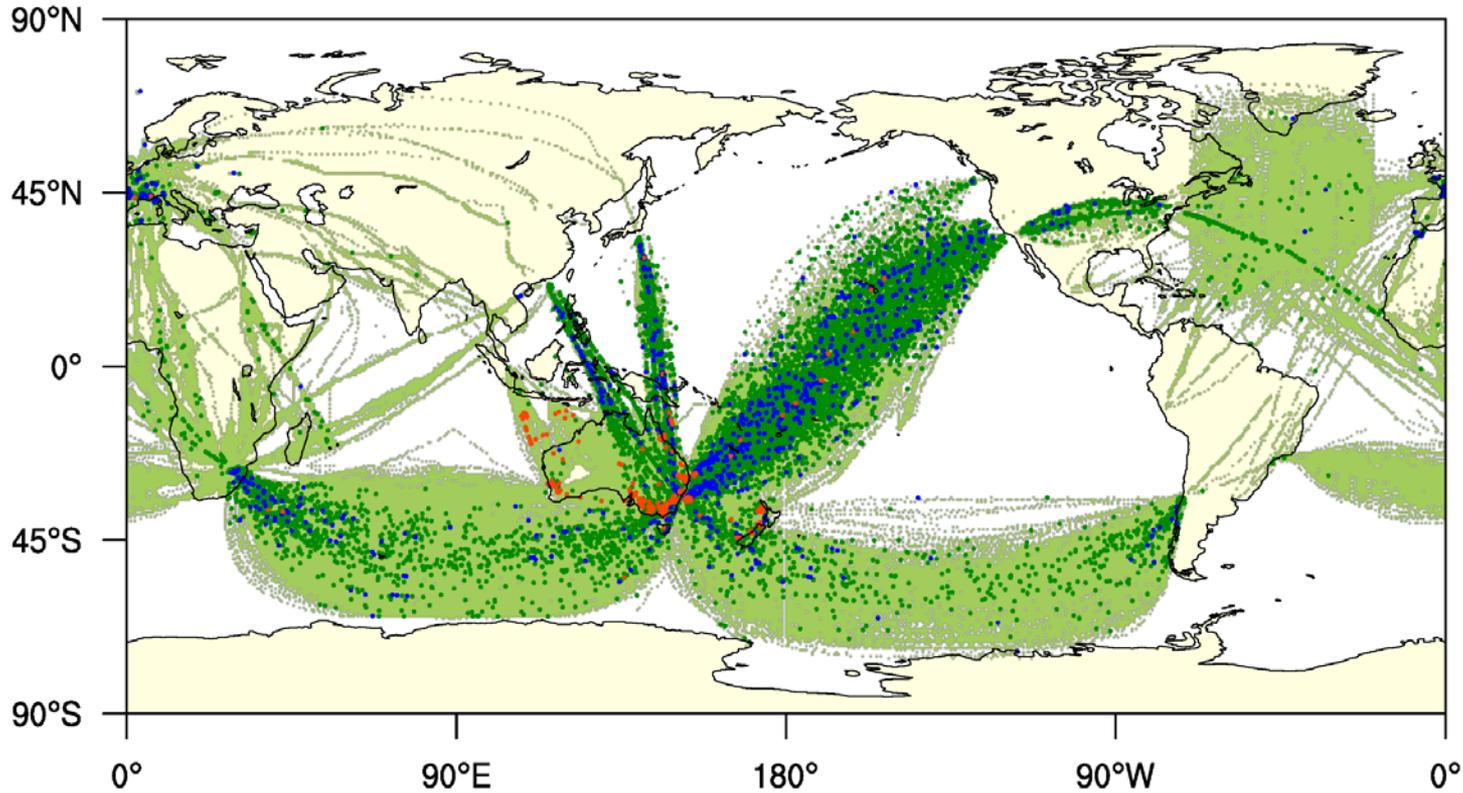

- Includes below FL280
- Includes “bad” aircraft
- Problems with positioning
- Spurious severe reports

# Importance of the EDR tuning

EDR-scale Ellrod3 before tuned

at 300 hPa for 20160106\_i00f18

Ellrod3

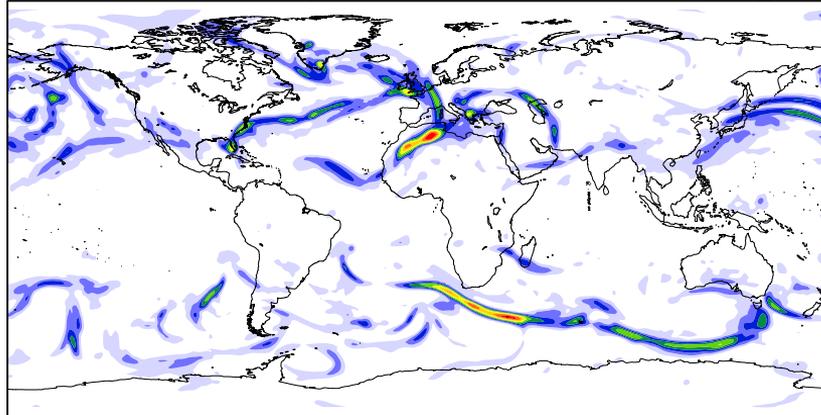

Uncalibrated

EDR-scale Ellrod3 after tuned

at 300 hPa for 20160106\_i00f18

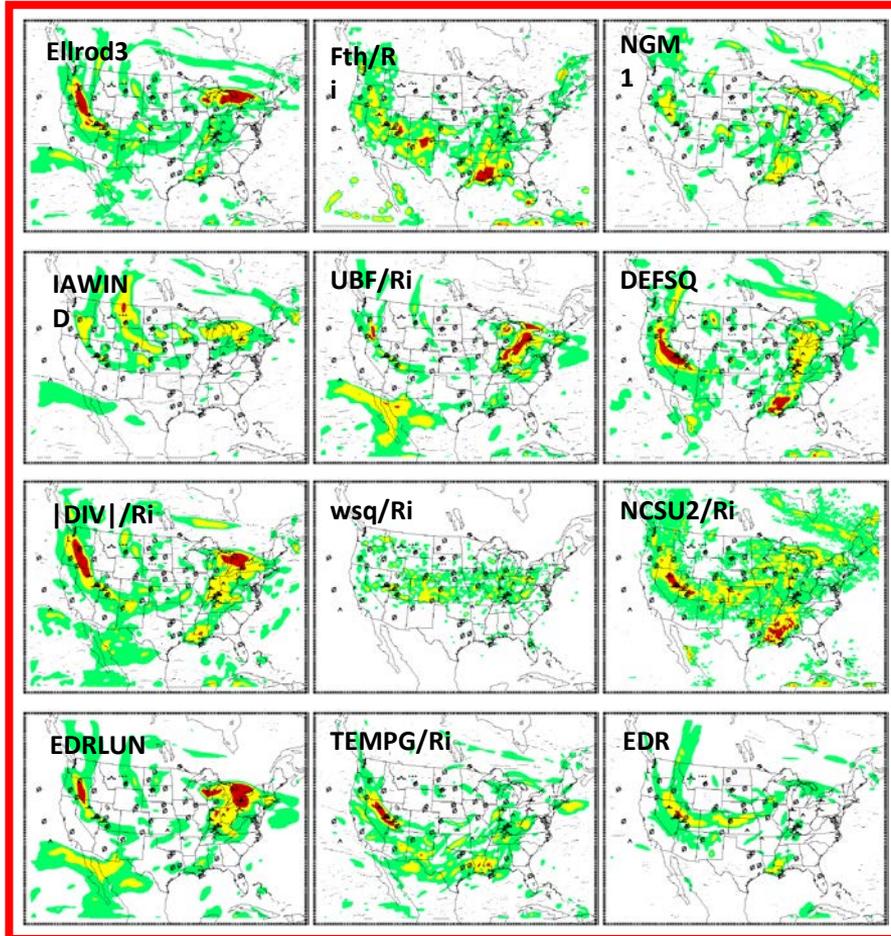

Ellrod3

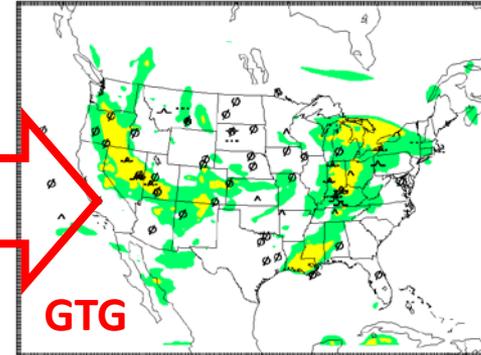

Calibrated

# GTG combination

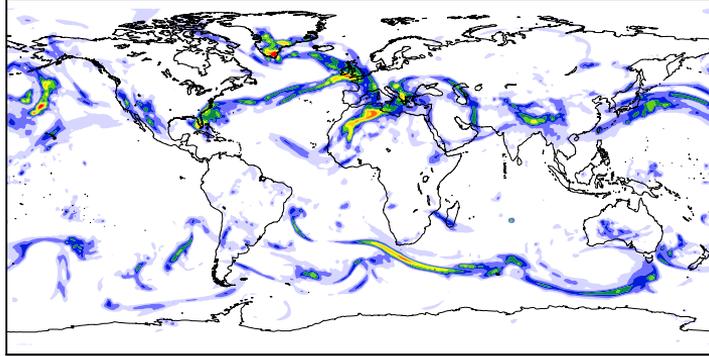

\* Probabilistic GTG:  
the percentage of CAT and  
MWT diagnostics  
exceeding a certain  
threshold at given grid  
points.

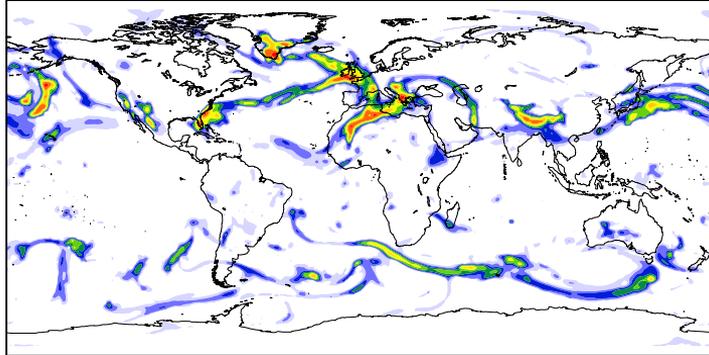

# Deterministic vs Probabilistic

Deterministic GTG at 300 hPa for 20160106\_i00f18

Probabilistic GTG at 300 hPa for 20160106\_i00f18

- Deterministic GTG
- Ensemble mean of EDR
- 15 CAT and 15 MWT
- Max EDR (CAT, MWT)

## The Best Probabilistic GTG

- Frequency (%):  
The number of CAT and MWT exceeding **0.14 EDR** value / 15 CAT, 15 MWT at given grid points
- Max Prob. (CAT, MWT)

\*\* Definition: A chance of having 10's km size eddy at the given grid box or area

# Next Steps for Global Turbulence

Improve data collection and quality control

Improve algorithm tuning and verification

Create global turbulence database

Define and explain probabilistic turbulence forecasts
