

# Accounting for land model uncertainty in NWP ensemble systems

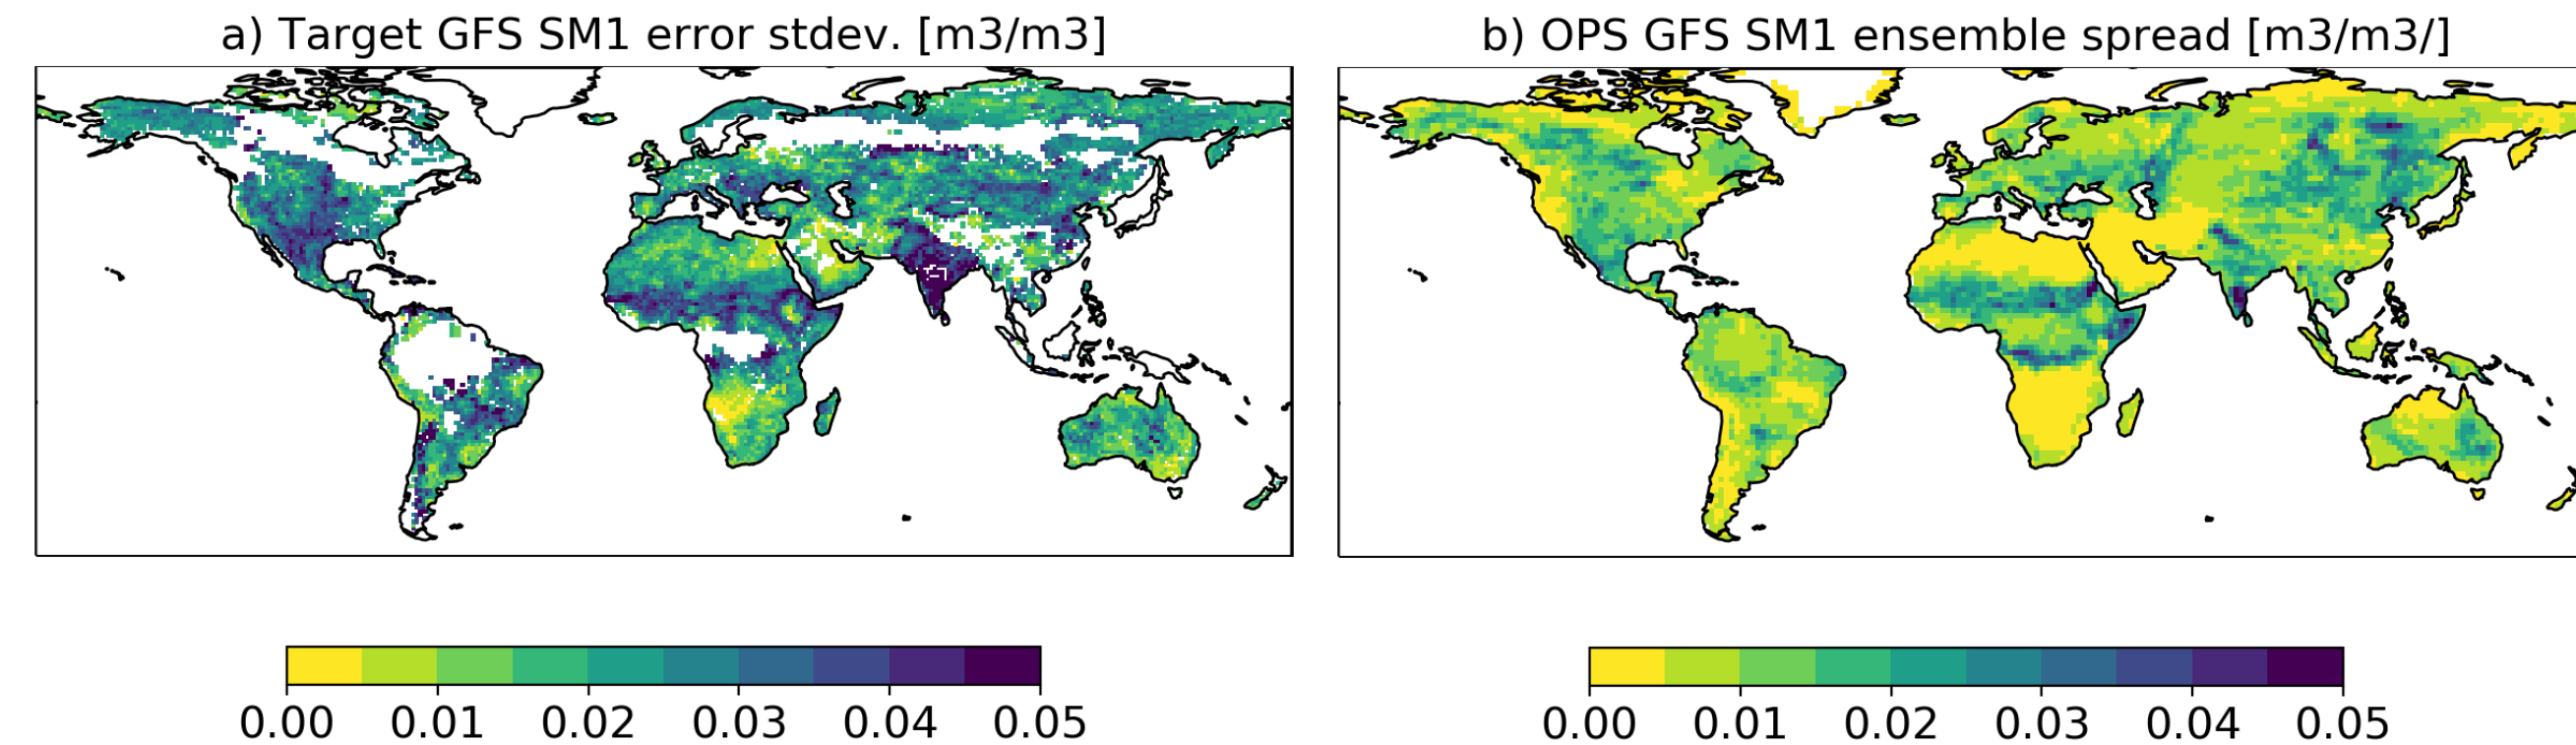

Clara Draper  
NOAA ESRL PSL, Boulder, CO, USA.

9th NOAA Ensemble Users Workshop, EMC, August 24, 2023.

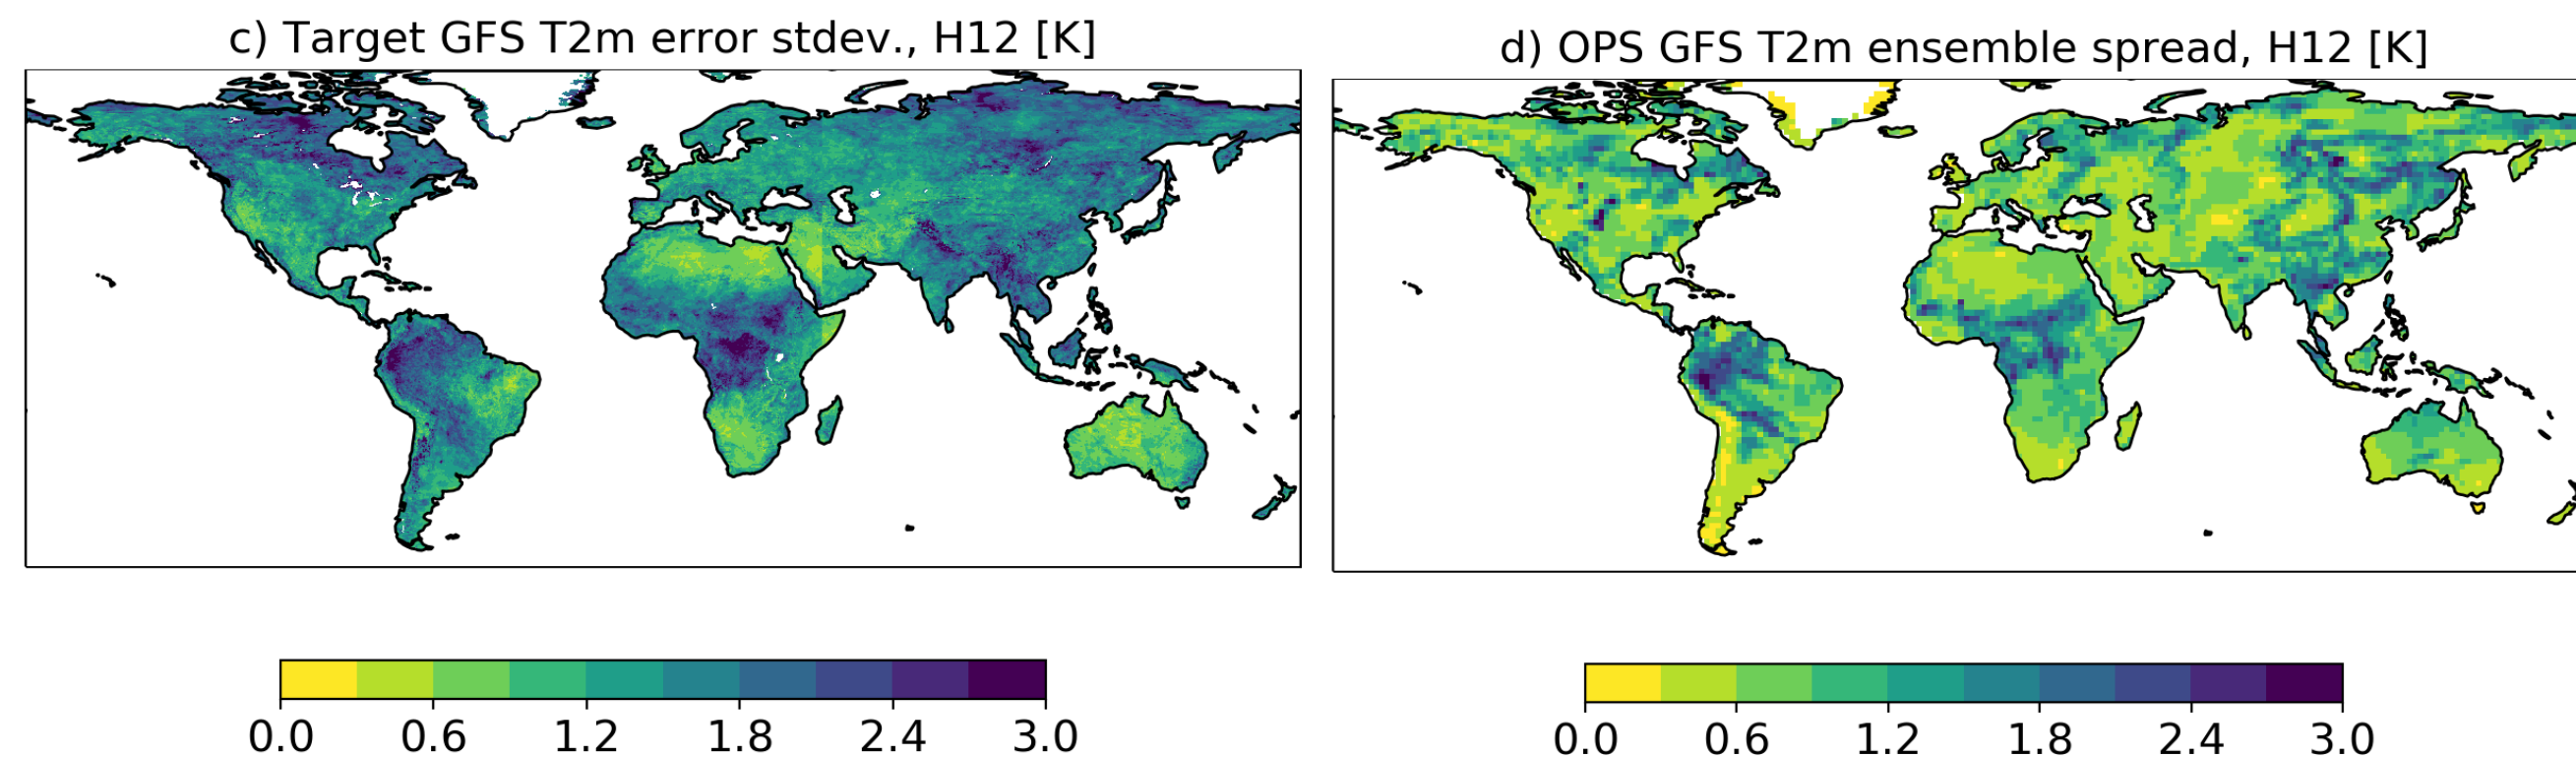

# Motivation

- NWP ensembles underestimate the forecast uncertainty at and near the land surface
  - Ensembles are not explicitly perturbed to account for land model uncertainty
  - Atmospheric forcing is also under-dispersed, but even with better atmospheric spread, still need to account for land model error
- Objective: better represent forecast uncertainty at/near land in NCEP's NWP (GFS) ensemble system
  - Improve ensemble-based model uncertainty estimates (e.g., forecast uncertainty over land)
  - Enable coupled ensemble-based land DA updates in the NWP ensembles

## Boreal summer forecast soil moisture, layer 1 (SM1) error standard deviation [m<sup>3</sup>/m<sup>3</sup>]

## Boreal summer daytime model T2m error standard deviation.

Target estimates, calculated using triple collocation (SM1), and comparison to ERA-5 analysis (T2m)

Ensemble standard deviation, from archived operational UFS output

# Land Model Physics and Error Propagation

- The land is strongly-forced (dissipative), and over time will converge to a state determined by its forcing
- Not chaotic, little information gained by perturbing initial conditions
- Land surface models do not simulate horizontal flow between grid cells
  - No horizontal flow of errors

Catchment Root-zone soil moisture simulation, from 3 ICs and identical forcing [m<sup>3</sup>/m<sup>3</sup>]

# Adding Land Model Uncertainty

- Test methods drawn from atmospheric and land ensemble DA communities:
  - State-pert: Stochastically perturb the SMC and STC *at each time step*  
(standard approach used in offline land DA platforms, such as LIS GLDAS)
  - SPPT-pert: Apply stochastically perturbed physics tendencies (SPPT) scheme to SMC and STC  
Motivation: use model physics to provide relationship between SM and ST deltas
  - Param-Pert: Stochastically perturb key model parameters controlling the land /atmosphere fluxes  
(here: vegetation fraction)  
Motivation: physically consistent perturbations in the land and atmosphere
- Tested each in a suite of experiments:
  - 30 member ensemble at C192, run 30 days from July 10, 2019
  - GFSv16 model, with Noah land model
  - DA cycling, hybrid 3DEnVar DA
  - Assimilating the standard atmospheric obs, using standard atmospheric stochastic physics

# Ens. Spread in Soil Moisture Layer 1 (SMC1)

Target (red) is best estimate of forecast error standard deviation (c.f, independent obs). Others are ensemble-based estimates from each experiment.

Soil Wetness Index = Soil moisture, scaled between dry (0) and wet (1) limits.

# Ens. Spread in Soil Moisture Layer 1 (SMC1)

- State-pert induces too much spread in dry regions. Due to soil moisture memory being longer in dry conditions.
- SPPT-pert can induce only a small amount of spread. Inherent limitation of the method.

- Param-pert looks reasonable. Spread could be inflated by perturbing additional variables.

Target (red) is best estimate of forecast error standard deviation (c.f, independent obs). Others are ensemble-based estimates from each experiment.

Soil Wetness Index = Soil moisture, scaled between dry (0) and wet (1) limits.

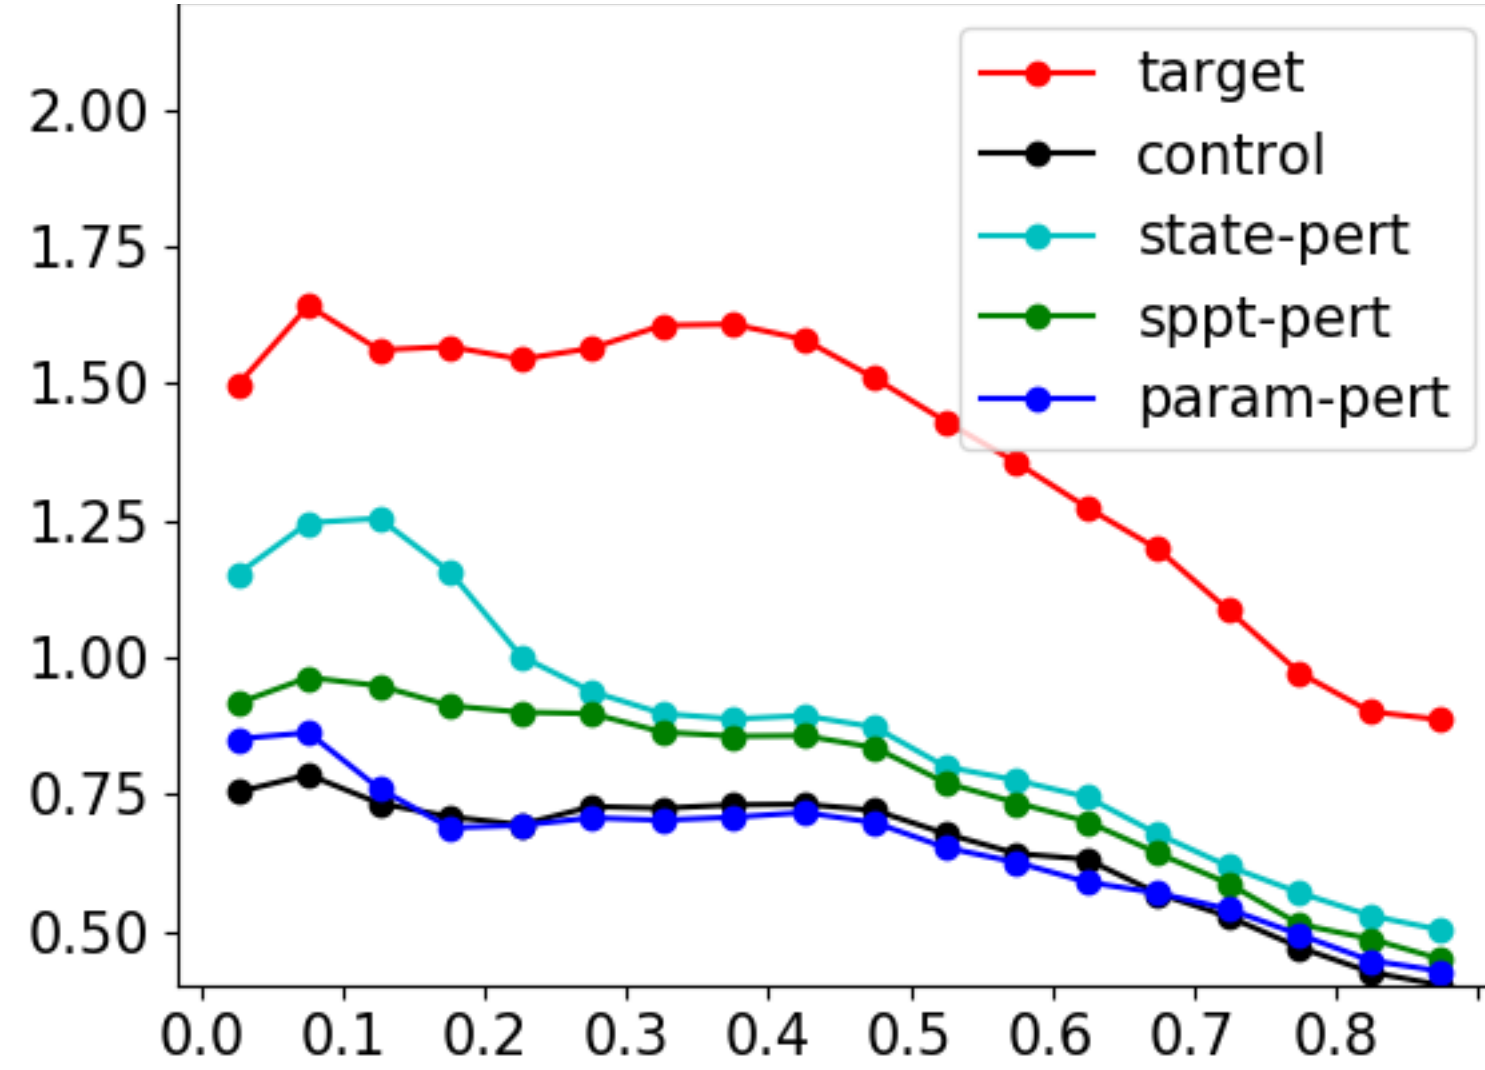

# Ens. Spread in 2m Temperature and Specific Humidity

## 2m Temperature

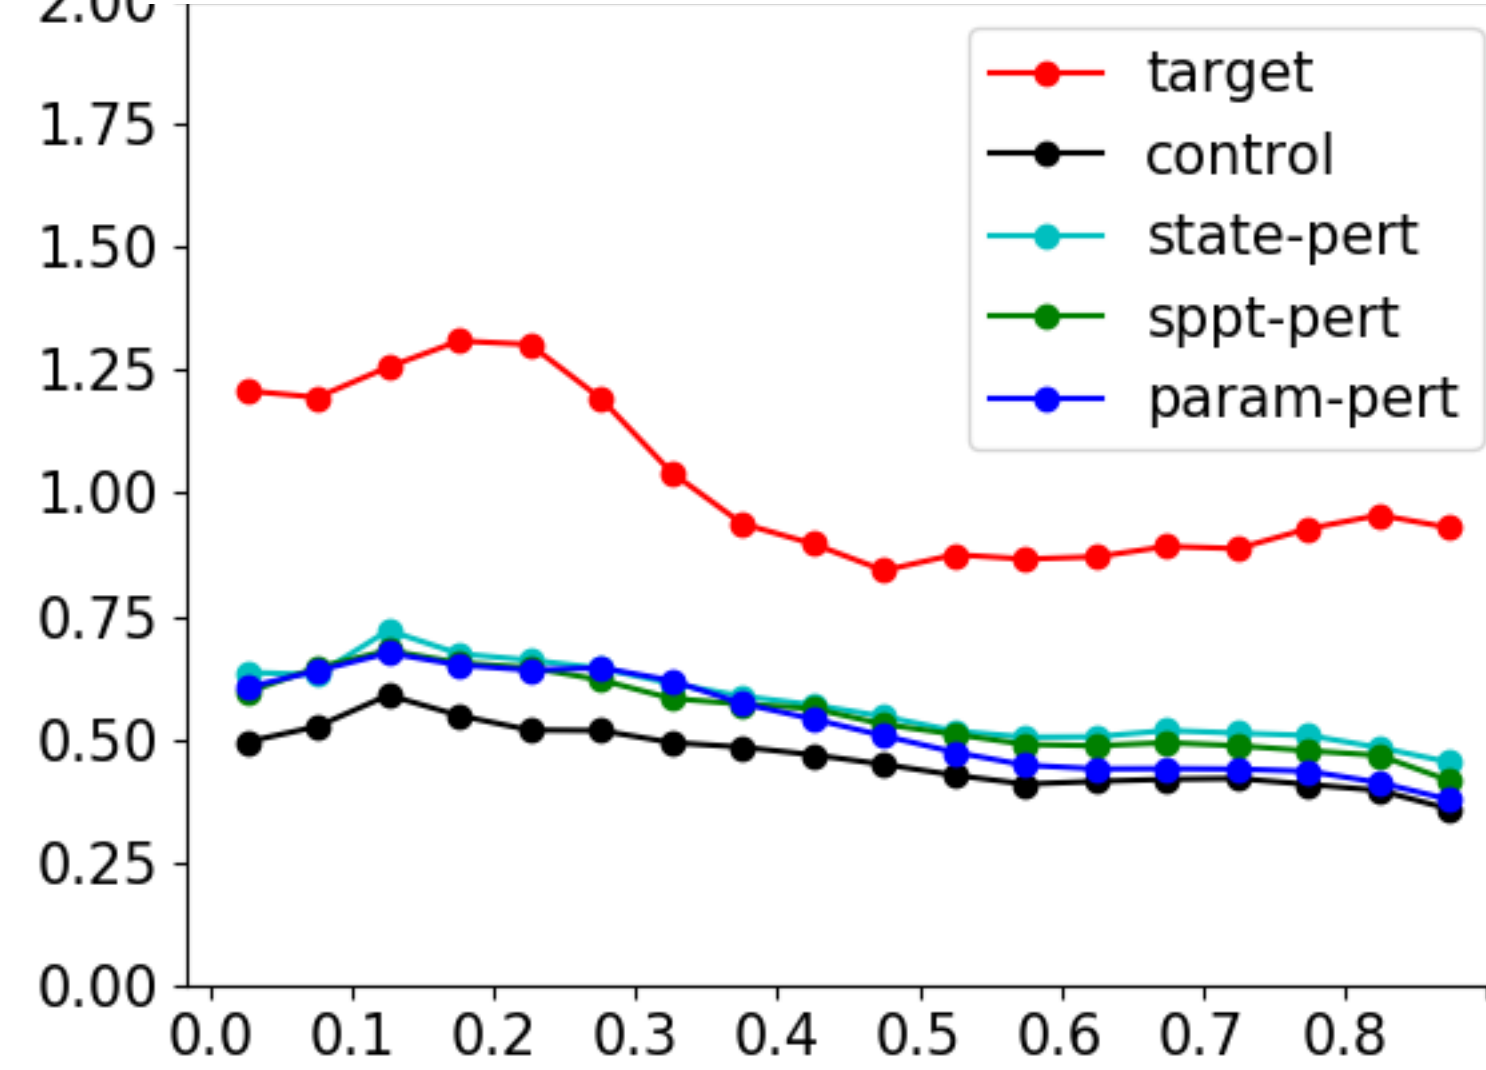

## 2m Specific Humidity

Nighttime

a) GFS T2m forecast uncertainty, H00 [K]

b) GFS Q2m forecast uncertainty, H00 [g/kg]

Results binned into 6 hour local time windows

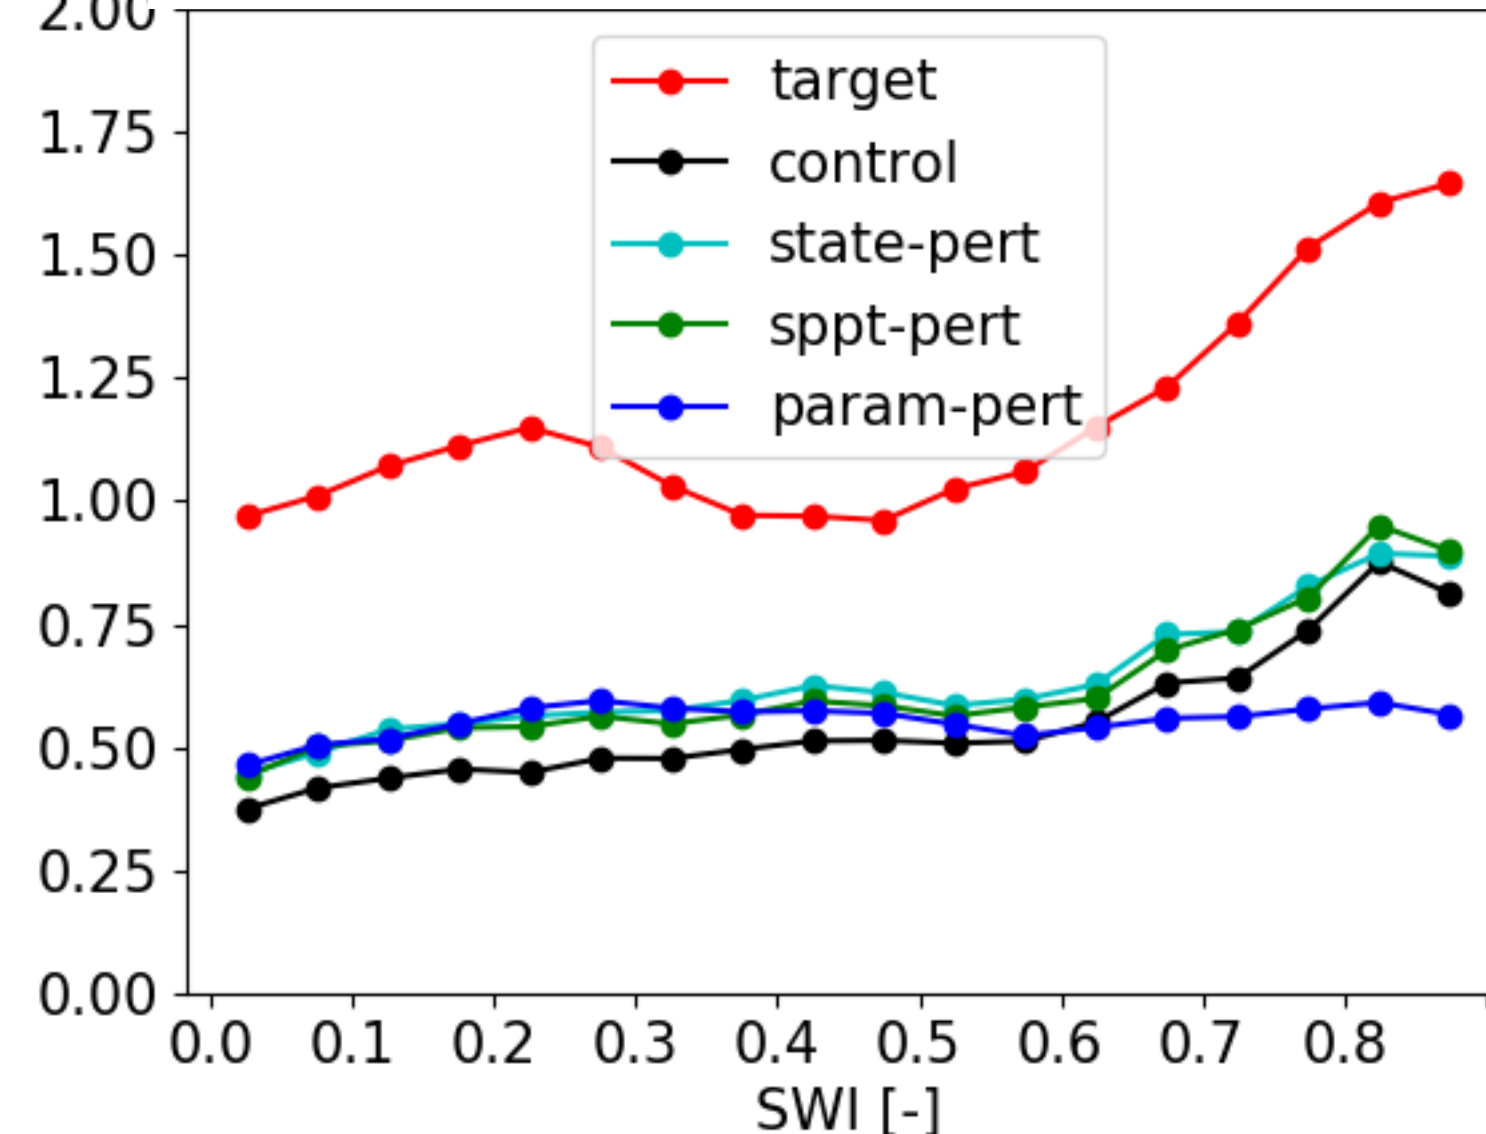

Target estimates calculated by comparison to ERA-5 analysis.

Daytime

c) GFS T2m forecast uncertainty, H12 [K]

d) GFS Q2m forecast uncertainty, H12 [g/kg]

Induced spread is generally limited in all experiments

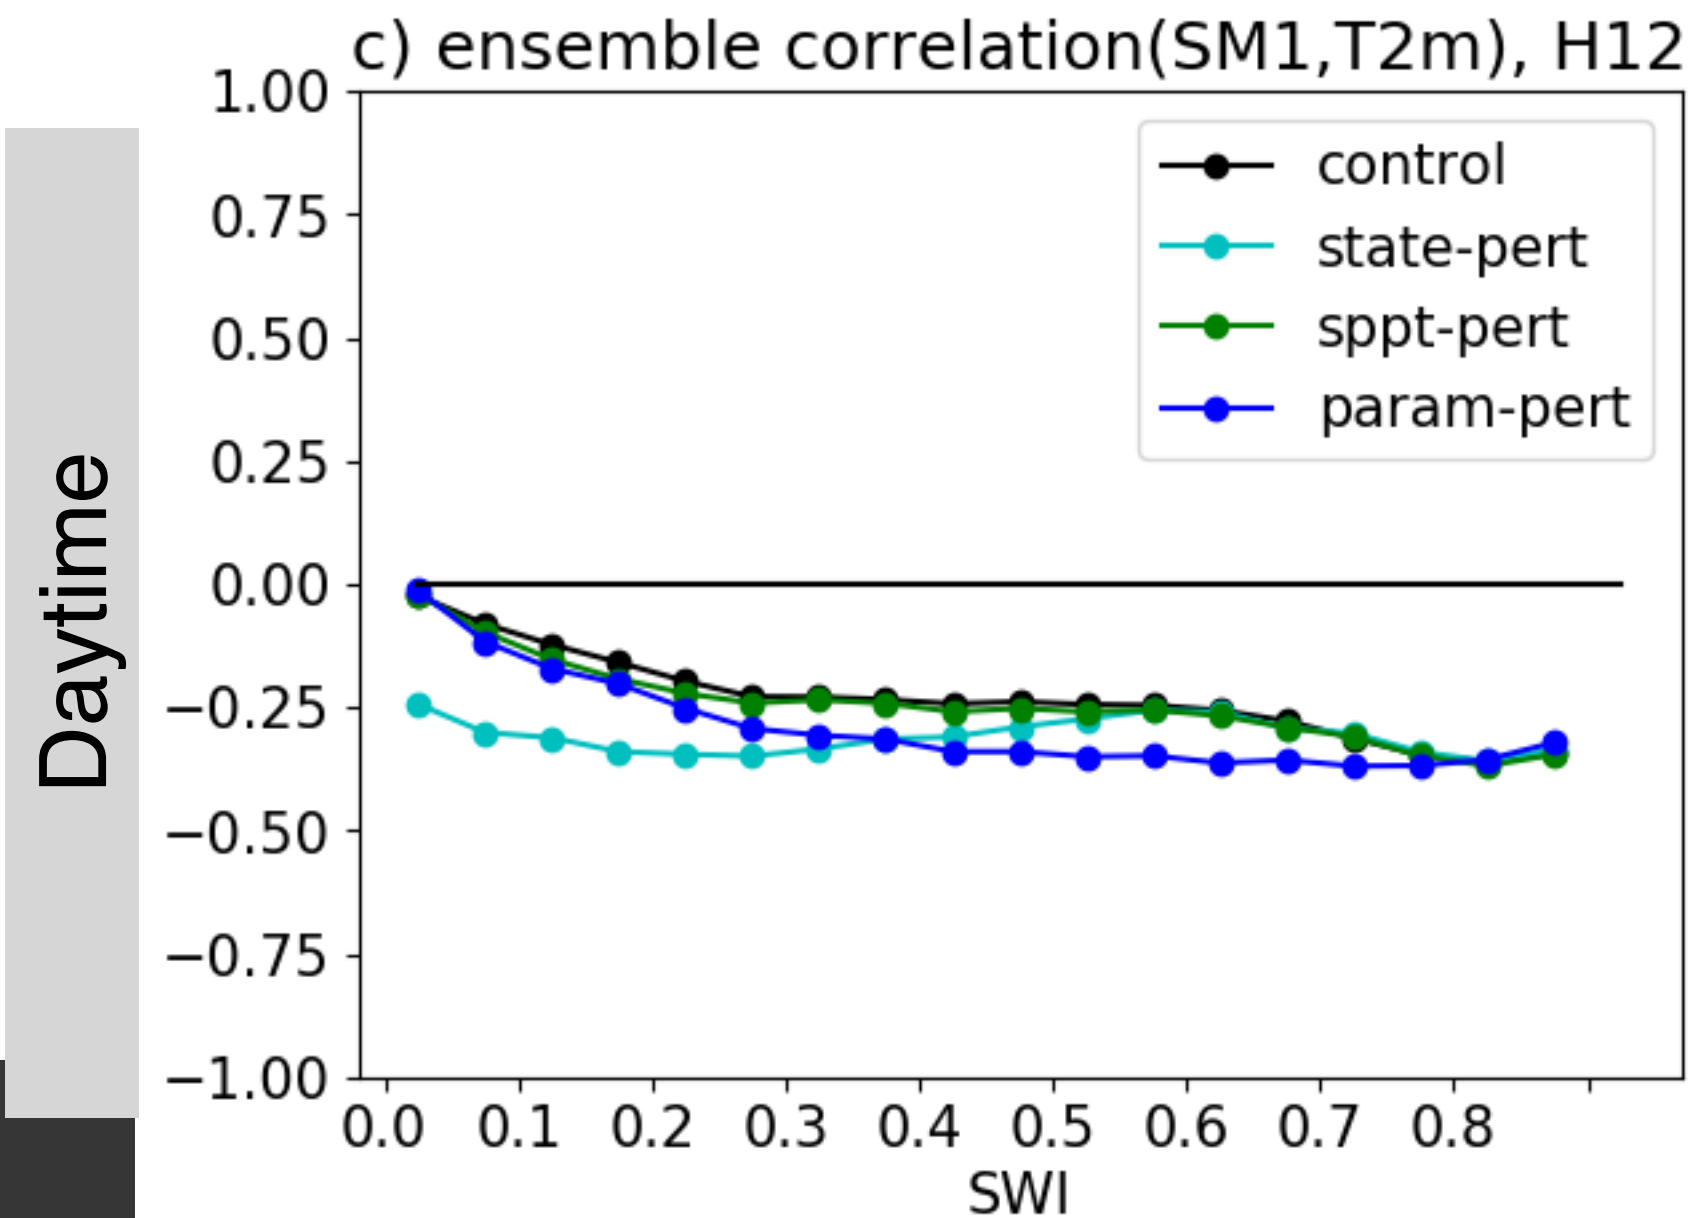

# Ensemble land/atmosphere correlations, soil moisture layer 1 (SM1)

- All experiments have incorrect positive SM1, T2m correlation in dry areas at night (problem in the model)
- State-pert strengthens correlations under dry conditions (when soil moisture drives land/atmosphere coupling)
- Param-pert experiment generally strengthens the correlations

### Correlations (SM1, T2m)

### Correlation (SM1, Q2m)

# Ensemble land/atmosphere correlations, soil temperature layer 1 (ST1)

- State-pert weakens the ST1, T2m correlations (atmosphere is driving the land/atmosphere coupling)
- Param-pert experiment again generally strengthens the correlations

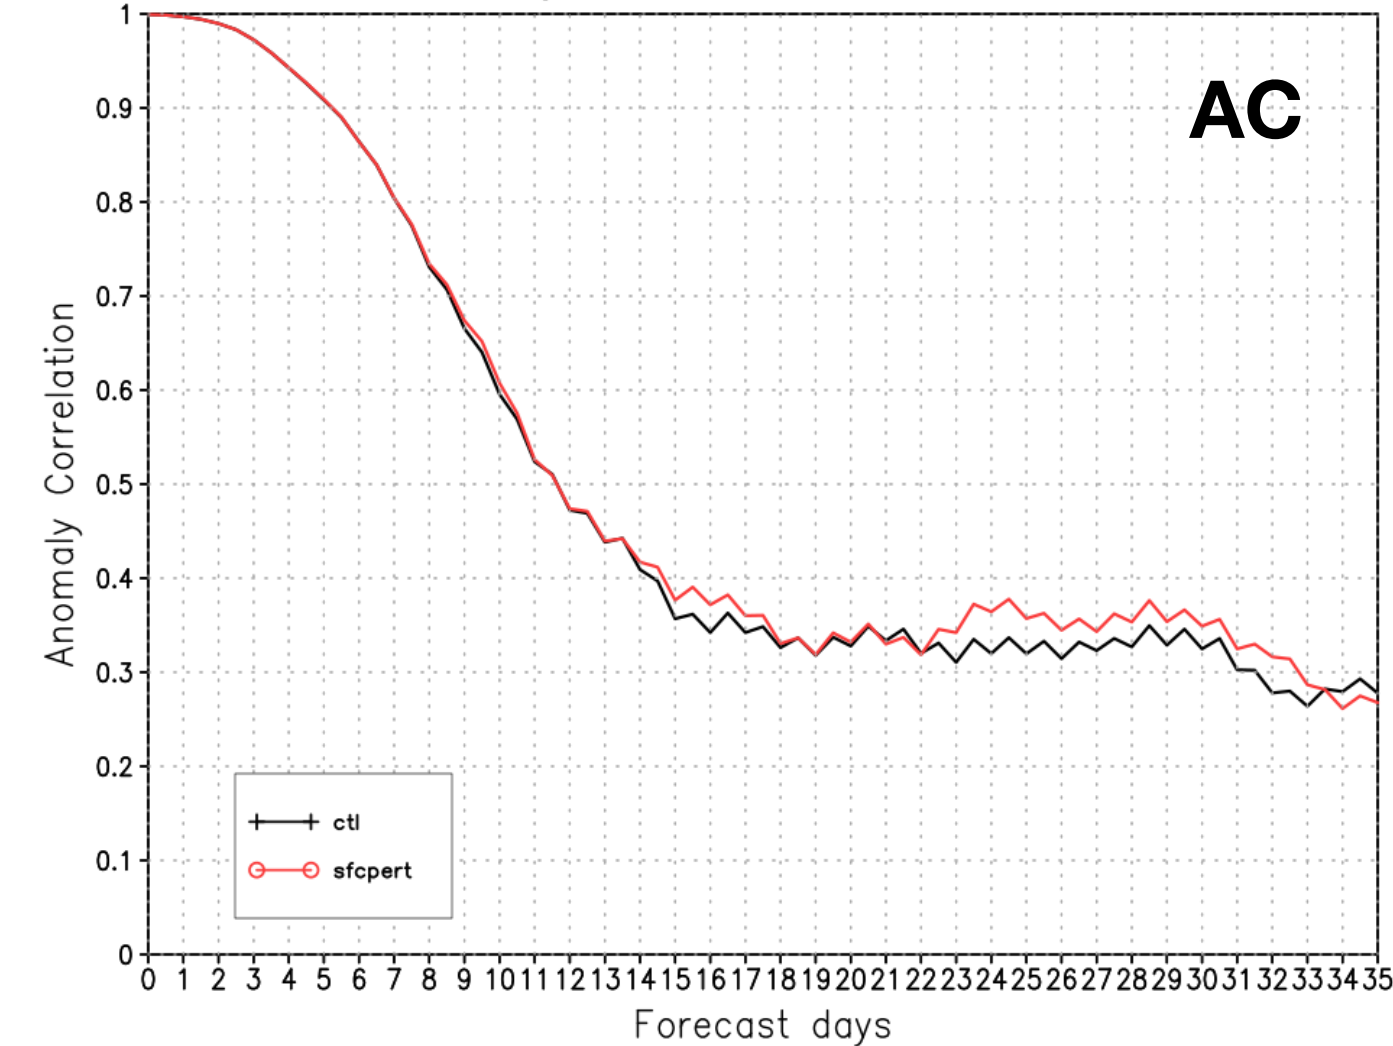

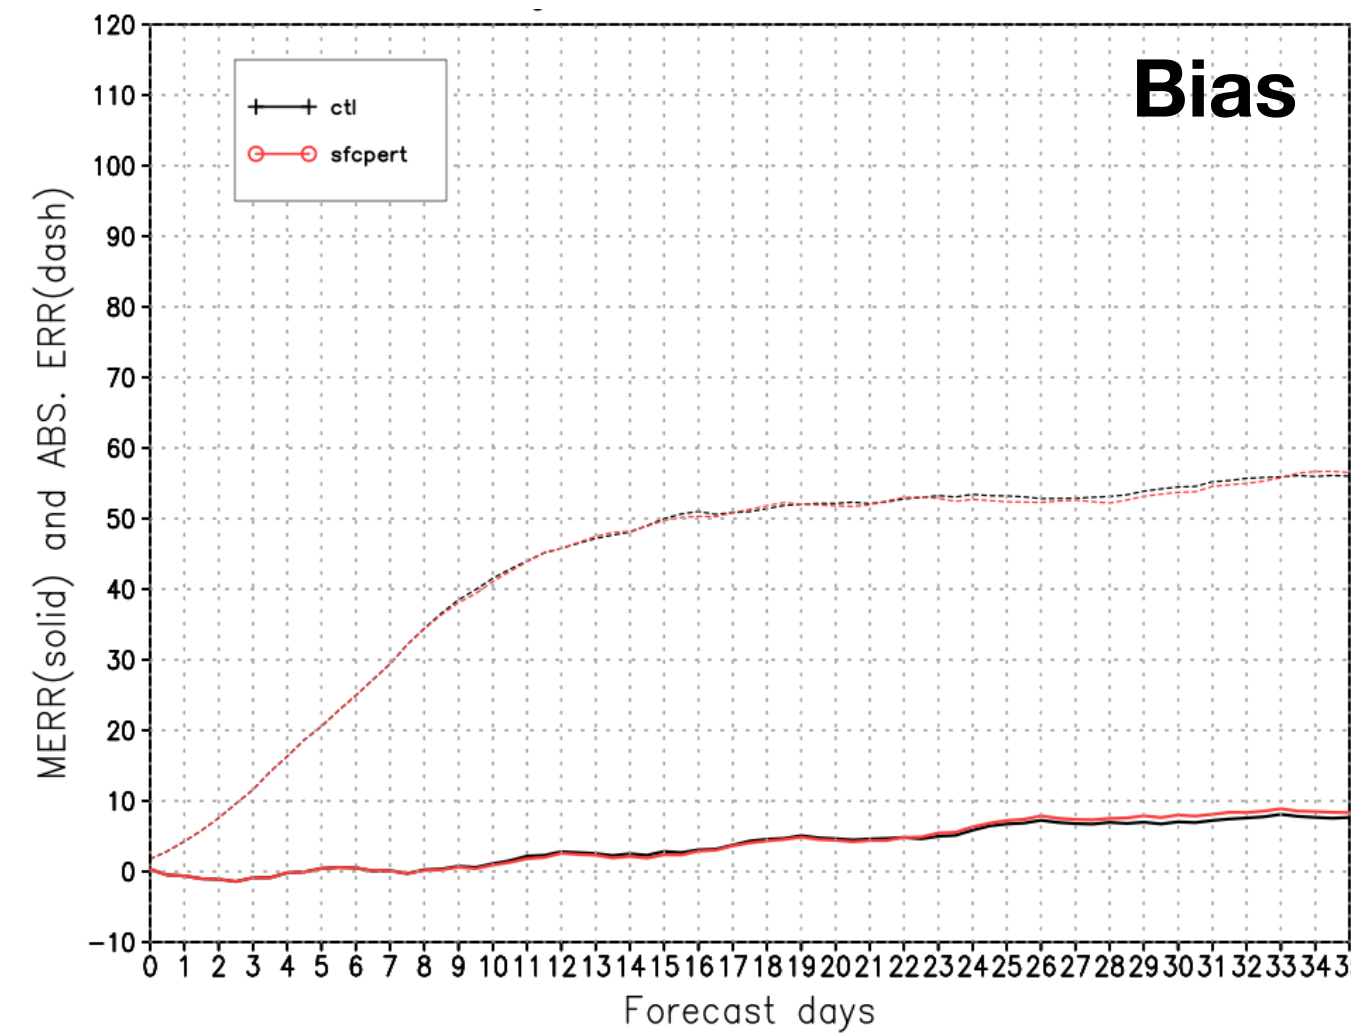

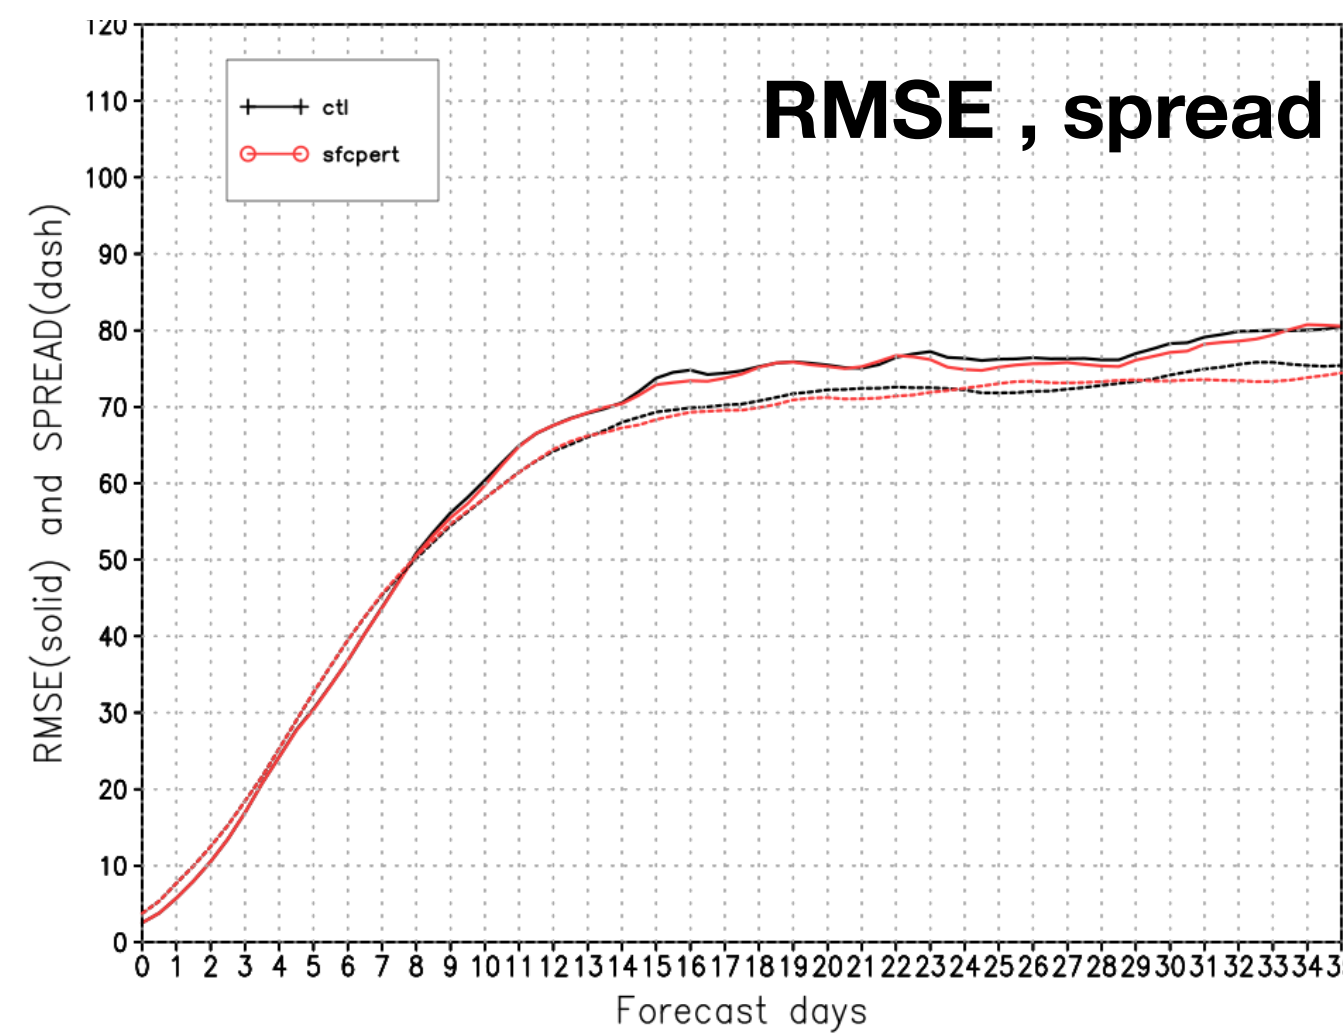

### Correlations (ST1, T2m)

### Correlation (ST1, Q2m)

# Forecast Experiments at EMC

NH  
500 hPA height

- Based on these experiments, colleagues at EMC tested perturbing vegetation fraction, roughness length, and albedo in longer forecast experiments (16 cases over a Boreal summer)
  - Limited impact on atmospheric spread and RMSE metrics (expected)
  - The land perturbations enhances pre-existing warm bias over Sahara (traced to roughness length perturbation)

C/o - Bing Fu, Hong Guan, Yuejian Zhu

# Summary and Conclusions (1)

- NCEP's GFS (and other) NWP ensemble system is under-dispersed at and near the land surface
  - Need to explicitly account for land model uncertainty when generating the ensembles
  - Land and atmosphere have very different dynamics, and different error growth behavior, cannot simply extend atmospheric methods
- For coupled data assimilation, cross-component correlations are very important
  - Perturbation methods targeting only one component will overestimate (underestimate) forecast error correlations where that (the other) component is driving the coupling

# Summary and Conclusions (2)

- For NCEP's GFSv16 NWP system, best results obtained by perturbing model parameters important to land/atmosphere fluxes
  - For land/atmosphere data assimilation, this directly targets fluxes between the components, creating error cross-covariances representative of errors in those fluxes
  - For applications interested in forecast uncertainty, generates more realistic spatial patterns in uncertainty than other methods
  - Work presented today was with Noah land model, working on implementing a similar scheme for Noah-MP (code is in place, but struggling to create perturbations that don't induce excessive spread in soil temperature)
- However (!), land model physics are highly non-linear; introduction of a land perturbation scheme will almost certainly change the ensemble mean land states
  - Difficult to evaluate mean land states (soil moisture!), and land/atmosphere models are instead tuned to give best atmospheric results from the model's mean state
  - Changes to the mean require re-tuning the ensemble, may not be feasible
  - May need to limit spread induced in land surface to avoid impractical changes in ensemble mean

Draper, C., 2021: Accounting for Land Model Uncertainty in Numerical Weather Prediction Ensemble Systems: Toward Ensemble-Based Coupled Land–Atmosphere Data Assimilation. *J. Hydrometeor.*, 22, 2089–2104, <https://doi.org/10.1175/JHM-D-21-0016.1>.

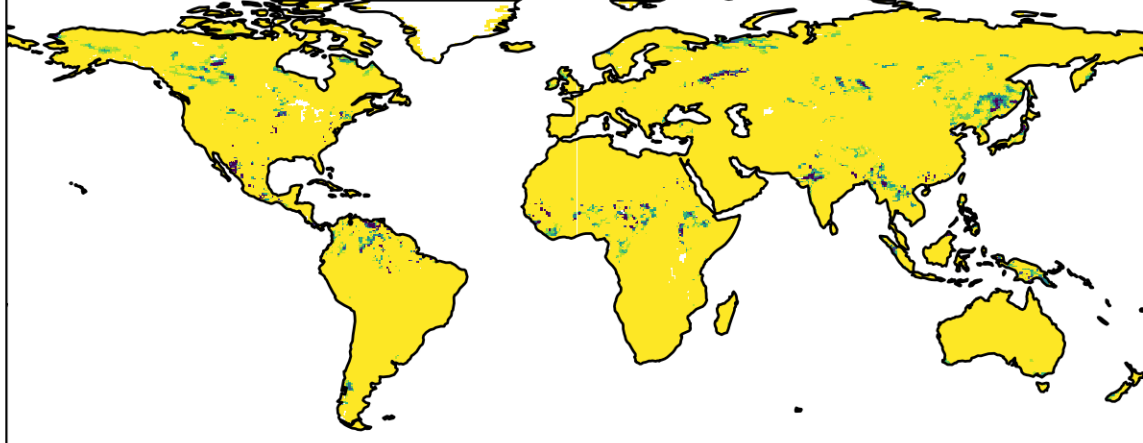

## Typical Offline Ensemble Spread

## Operational GFS Ensemble Spread

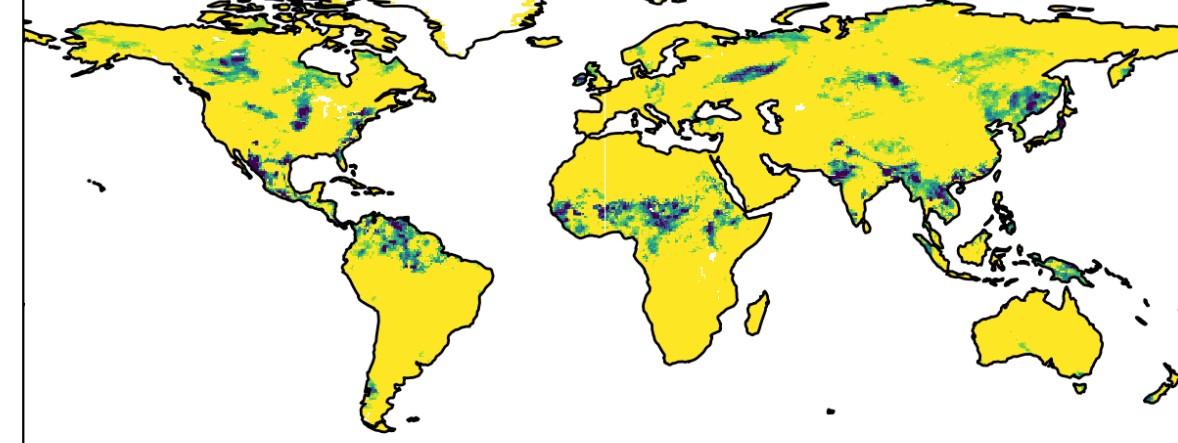

# Atmospheric Forcing Uncertainty

- Left: example uncertainty estimates as used in a typical offline land DA system (perturb a single atmospheric realization using perts. drawn from best estimate of the error distribution)
- Right: example uncertainty estimates from the GFS ensemble (estimates from ensemble of GFS forecasts)
- Atmospheric forcing spread in GFS likely under-estimates forecast error in radiation
- Full GFS ensemble produces more realistic spatial error structure

a) Precip. ensemble spread, offline [mm/day]

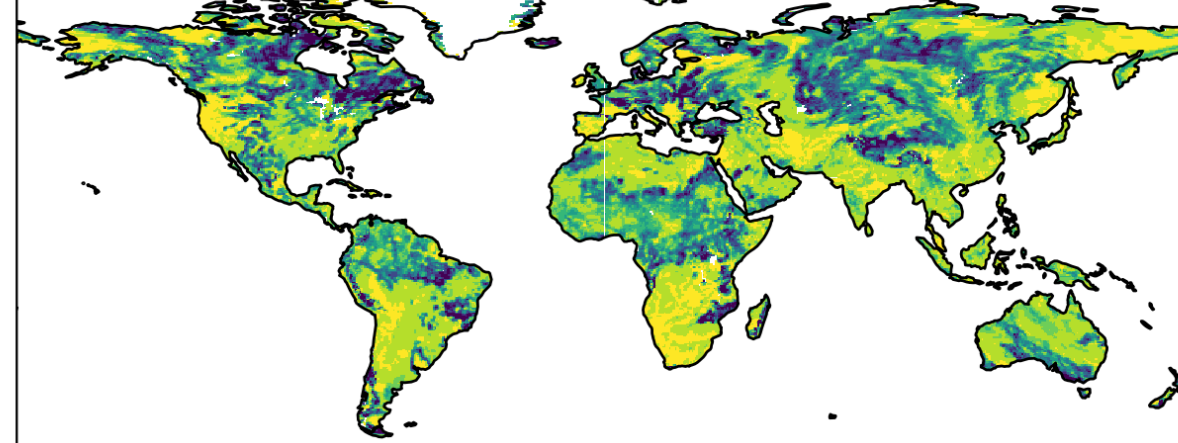

b) Precip. ensemble spread, coupled [mm/day]

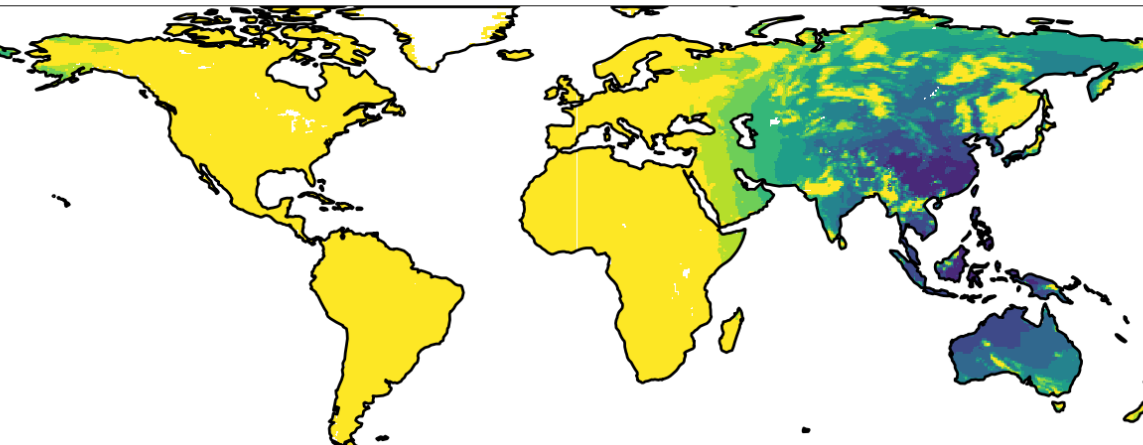

c) LWd ensemble spread, offline [W/m2]

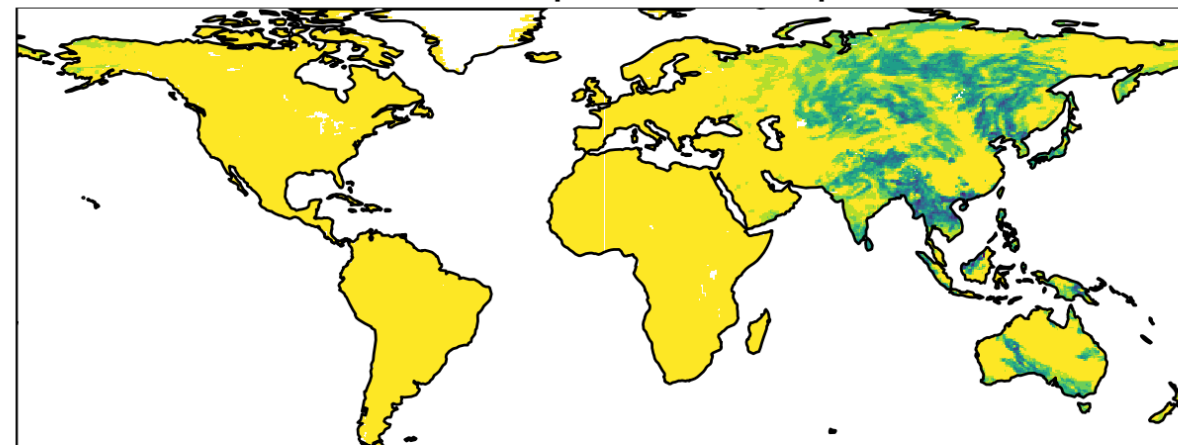

d) LWd ensemble spread, coupled [W/m2]

e) SWd ensemble spread, offline [W/m2]

f) SWd ensemble spread, coupled [W/m2]

# Summary and Conclusions (2)

- Offline (land-only) ensemble-based DA systems, recommendations:
  - Replace current method of regularly perturbing model states, as creates unrealistic spatial patterns
  - Use atmospheric ensemble forcing, in place of perturbing a single atmospheric realization  
... or for atmospheric systems, do the DA within the atmospheric ensemble
- Coupled data assimilation, recommendations:
  - Use ensemble perturbation approaches that directly target fluxes between the components, to create error cross-covariances representative of errors in those fluxes
  - Perturbation methods targeting only one component will overestimate (underestimate) forecast error correlations where that (the other) component is driving the coupling
- NCEP's GFS NWP system:
  - Applying the parameter perturbation approach (expanded to perturb veg. fraction, roughness height, and albedos)
  - Developing EnKF DA of 2m variables to update model soil moisture and temperature (for now, focus on soil temperature only, due to soil moisture / T2m model error)
  - Looking into impact on ensemble mean and skill (EMC colleagues)
